Intro to Internet Computing

Project 5

For this project, it was my first-time using PHP. I had some trouble doing some things that I could normally do on another language like python and C++. For example, I wanted to create a function that had the $_POST["num"] as one of the parameters but I ran into errors, so I gave up on doing that. I was also struggling on how to create a counter. During this process, I learned that the php code would reset after I clicked the submit button. So, when I went to put a loop of some sort into the php scope, I could initially click the submit button but then I could not leave the loop to submit another guess because the code for the button was in the html scope. I just had a hard time on figuring that one out.

I tried to decorate my page with my own styles this time instead of using a bootstrap. I want to try out my skills rather than copy and paste something that looks nice. Throughout this project, I can say I learned a lot because this is another angle about web designing that I didn't know existed. Reading through the Zybook really gave me a better idea of what I'm supposed to do. I still had to watch a couple videos about POST, GET, and SERVER to get a grip on them because the book didn't take a lot of time explaining them.
